Abstract: Objective: To determine the frequency of Urinary tract infections in children presenting with fever without a focus – a tertiary care hospital experience.

Material and Methods: It is a descriptive cross sectional study to find out the frequency of UTI conducted from 26th April to 25th October 2013. Patients of either gender, 1 month to 36 months of age, presenting with the complaints of fever without focus were included. History and physical examination were done; urine sample was collected for analysis and culture. Data was recorded on a pre designed Proforma. Mean and standard deviation for quantitative, frequencies and percentages for qualitative variables were computed. Stratification was done to observe the effects of modifiers on outcome. Post stratification chi square test was applied and p value ≤ 0.05 was considered as significant.

Results: Among total 126 study subjects 62 patients were male. The mean age was 13.96 ± 8.56 months. Mean age of patients was 13.88 ± 6.50 months and 13.97 ± 8.86 months for patients with and without UTI respectively. Among patients with urinary tract infection, 9(52.9%) were male and 8(47.1%) were female patients. Age of 9(52.9%) patients was ≤13 months and age of 8(47.1%) patients was >13 months. There was no significant association of UTI observed with gender (p = 0.741) and age (p = 0.794).

Conclusion: UTI is a common infection that can be easily missed in young children. Screening patients at risk can lead to proper diagnosis and a reduction in morbidity.

Keywords: Urinary tract infection, Fever without focus, Urine culture, Urine DR, Morbidity, Bacterial infection.

INTRODUCTION

Fever without focus is an obscure clinical phenomenon for young children [1] It specifies a child with history of documented fever of at least 1 week duration without any compelling examination findings [2]. In approximately, 20% of children who present in outpatient clinics with significant history of fever, no focal point is identified after meticulous clinical assessment [3-5].

The causative factor can be either bacterial or viral. The incidence of bacterial infection varies from 3% to 15% in these cases [6-8].

In children core body temperature of >37.7°C (100.4°F) is considered significant enough for evaluation of any serious occult bacterial infection including UTI [8].

UTI is an infection of any part of urinary tract and occurs when the tract is invaded by bacteria. It is subdivided into two types. 1. Upper urinary tract infection (involving kidney and ureters) 2 lower urinary tract infection involving (urethra and bladder). History and physical examination alone cannot differentiate between these two types. A number of laboratory and radiological investigations are required to confirm either of the two types [9-11].

Urinary tract infections (UTIs) are a common cause of morbidity in children [12, 13]. If UTI is missed or inappropriately treated, the long term sequelae might lead to renal scarring and dysfunction [14]. UTI is five times more common in males compared to females from birth till 3rd month which is contrary to the incidence later on in life [15].

Urinary tract infections (UTIs) are almost always occult in febrile children younger than 2 years of age [8]. In Pakistani population, Rehman et al. reported that the frequency of UTI among children is close to (37.5%), out of which 36 (9.6%) were male and 339 (90.4%) were females. 48.5% of his patients were younger than 3 years [2].

The morbidity of the urinary tract infection (UTI) in infancy is very high resulting in renal damage with symptoms ranging from mild hypertension to end stage renal failure [16, 17]. In childhood, UTI is 2 to 4 fold more prevalent in girls than in boys, and 5% of school girls have UTI during their school years [18, 19]. In children, within one to two years of the first diagnosed UTI, renal parenchymal defects are noticed in 3-15% of children.

Attempts to estimate the prevalence of UTI in children age 2 months to 2 years of age with no apparent source of fever have had varying success. For example, Shaw, Gorelick, McGowan et al. investigated prevalence rates of UTI among females under 2 years old and males under 1 year of age who

had a fever of equal to or greater than 38.5 degrees Celsius [20] Caucasian females were found to have a 16.1% prevalence rate of UTI. This finding is similar to the 16.0% prevalence rate of UTI among Caucasian females whose highest temperature was equal to or greater than 39 C. documented by Hoberman et al. [20].

The best and reliable way to diagnose a urinary tract infection is culture but it takes a lot of time for the report to finalize. If the urine dr report shows a combination of ≥10 WBC/hpf and bacteriuria (on either centrifuged or uncentrifuged urine) [21] along with more readily available urine dipstick (positive for either leukocyte esterase or nitrites) the sensitivity reaches upt0 88% [22]. Treatment should be started immediately upon detection of any positive result.

The aim of this research is to know the incidence of UTI as a cause of fever without focus in our setup. This will not only help in diagnosing UTI but will also help in preventing complications associated with untreated UTI. The data might prove conducive in developing a departmental protocol for performing urine analysis in all children presenting with fever without focus thereby ensuring timely diagnosis, treatment and prevention of future complications associated with UTI.

MATERIALS AND METHODS
The study was conducted at Pediatric Department of Liaquat National Hospital, Karachi, from 26th April 2013 to 25th October 2013. The sample size of 126 patients was included in this study. It was a descriptive cross sectional study. Non-probability consecutive sampling was used as the method for patients’ enrollment in the study. Patients of either sex, having ages between 1 – 36 months, presenting with fever of less than week duration without any localizing focus were included. All children who have any localizing focus like rash, respiratory, cardiological, neurological, abdominal, musculoskeletal and urogenital sign and symptoms. Those who have received antimicrobial agent within last 48 hours, or undergone bladder catheterization within 48hours, or any surgical procedure of urinary tract in the past or have any urogenital abnormalities were excluded.

A written informed consent was taken from parents/guardians of each patient. Patient’s history and physical examination was conducted by the principle investigator. After thorough clinical evaluation, urine sample was collected for analysis and culture by clean catch method from each child. Urine analysis was done on Urysis 2400. Urine specimen was cultured on CLED agar plate (cysteine lactose, electrolyte deficient).

Data was analyzed using Statistical Package for Social Sciences (version 21). Mean and standard deviation were computed for the quantitative variable i.e. age. Frequencies and percentages were computed for the qualitative variables i.e. gender, fever, circumcision, urine C/S, urine DR, and UTI. Effect modifiers like age and gender were controlled by stratification to observe the effects of these modifiers on outcome. Post stratification chi square test was applied and p value ≤ 0.05 was taken as significant.

RESULTS
126 children of either gender ranging from age 1 month to 36 months and had complaint of fever for less than one week duration without any localized focus of infection were evaluated to determine the frequency of Urinary tract infections (UTI).

Among total study subjects, 62 (49.2%) children were male and 64 (50.8%) patients were female. Among male patients, 57(91.9%) patients had circumcision done and not yet done in only 5(8.1%) patients. The mean age was 13.96 ± 8.56 months, 63(50%) patients age ≤13 months, the mean age of these patients was 6.95 ± 3.46 months. Rests of the 63(50%) patients aged >13 months, the mean age of patients in this group was 20.97 ± 5.99 months.

Among overall 126 patients, the urine culture sensitivity was found organism isolated in 17 (14%) patients. 10 patients out of 17 had significant growth of E coli (105 organisms/ HPF) Urinalysis reports showed presence of pus cells in 13 patients and not found in 113 patients.

Positive urinary tract infection showed that age of 9 patients was ≤13 months and age of 8 patients was >13 months. However, there was no significant association of UTI with age (in months) (Table 1) (p = 0.794).

Among total 17 patients with positive urinary tract infection, 9 were male and 8 were female patients. The results showed that no significant association of UTI was observed with gender (Table 1) (p = 0.741).

DISCUSSION

Majority studies have quoted a positive Urine culture (>100,000 CFU/ml) as being diagnostic of UTI in addition to pyuria (more than 5 white cells per high powered field on microscopy) and bacteriuria. Presence of both pyuria and bacteriuria from a fresh urine sample is highly indicative for possible UTI although not diagnostic [23].

Numerous studies have attempted to determine the prevalence of UTI in infants and young children. A comprehensive review of the literature was submitted by the Urinary Tract Subcommittee of the AAP in 1999. The Committee concluded 5% prevalence in children age group 2months to 2years of age [24].

Girls are more prone to develop urinary tract infection owing to a shorter urinary tract. Thus all females from age 3 to 24 months with a significantly higher core body temperature and no other specific symptoms should have their urine analysis and culture done. Some researchers have also urged the need to do urine studies for highly febrile boys between 3 to 24 months of age [11]. In our study, the no such difference of age 9 patients age less than or equal to 13 months and 8 patients aged more than 13 months.

Pakistan is a developing nation with majority of population at risk of serious occult infections, urinary tract infection being one of them. A study from Yemen cotes 375 out of 1000 (37.5%) febrile patients were diagnosed as having UTI [25], the percentage of which is quite low in comparison to other studies [1]. Our study showed no significant difference with respect to gender which is different from some other studies showing 1:10 male to female ratio [26]. In yemen study male to female ratio was 1:26 [25] which might be due to early circumcision practices in that country. In our study children less than 3 years constitute less than half of the total infected cases similar to other studies [27]. This might be due to toilet training issues at this early age [28].

Studies show an association of UTI with fever in 91% cases [29]. Color, smell or turbidity of urine had no relationship with UTI. Around 88% of cases of UTI had no change in color or smell of urine [29]. Recurrent episodes of UTI were associated with poor compliance to initial treatment for UTI, infrequent follow-up visits and anatomic abnormalities of urinary tract. In our study associated other symptoms were urethral discharge and palpable urinary bladder comparable to other studies with similar incidence [30].

In this study, after screening 126 children, the overall prevalence of UTI (boys and girls) was calculated to be 13.5%, whereas the prevalence of UTI in boys was 14.5% and in girls it was calculated to be 12.5%. In Jordan, a study was conducted to determine conditions that result in pediatric nephrology consultations in the academic hospital of Jordan University in the age group from one day to 16 years and found that urinary tract infections account 14.2% of consultations [31].

CONCLUSION

As UTI in children often goes undetected owing to infrequent symptomatology a coherent clinical approach is required in which all febrile children with no other focus of infection be screened for the presence of this occult infection. It will lower the incidence and will prevent children from developing long term renal damage.

LIMITATIONS OF STUDY

• Unicentric study.
• Limited sample size.

CONFLICT OF INTEREST

Declared none.

INTRODUCTION

Urinary tract infections (UTIs) are almost always occult in infants and young children. Studies show an association of UTI with fever in 91% cases [3-4]. Age is a significant factor in the development of UTI. Infants are more vulnerable due to immature immune and urinary systems. The incidence of UTI is higher in girls than boys. In general, the prevalence rate of UTI is higher in males than females, especially after 1 year of age. However, during the first few months of life, UTI is more common in females [5-7].

METHODS

Aims and objectives

This clinical study was conducted at National Hospital, Karachi, from 26th April 2013 to 25th October 2013. The study was carried out by 2 pediatricians, in cohort design. The study was approved by the Ethics Committee of the Hospital. The signed informed consents were obtained from the parents. The inclusion criteria were: children of either gender ranging from age 1 month to 36 months, presenting with fever of at least 1 week duration without any localized focus of infection were enrolled in the study. The children who had UTI in the last three months and had complaint of fever for less than one week were excluded from the study. The children who have received antimicrobial agent within last 48 hours, or musculoskeletal and urogenital sign and symptoms. Those children were excluded from the study. The children who have receive antimicrobial agent within last 48 hours were excluded from the study. The data was collected according to the pre-determined data collection sheet. Positive urinary tract infection showed that age of 9 patients was less than or equal to 13 months and 8 patients were more than 13 months. However, there was no significant association of UTI with age [8].

MATERIALS AND METHODS

To estimate the prevalence of UTI in children age 2 months to 12 years, a case-controlled study was conducted at National Hospital, Karachi, from 26th April 2013 to 25th October 2013. The study was approved by the Ethics Committee of the Hospital. The signed informed consents were obtained from the parents. The inclusion criteria were: patients of either gender ranging from age 1 month to 36 months, presenting with fever of at least 1 week duration without any localized focus of infection were enrolled in the study. The children who have received antimicrobial agent within last 48 hours, or musculoskeletal and urogenital sign and symptoms. Those children were excluded from the study. The children who have receive antimicrobial agent within last 48 hours were excluded from the study. The data was collected according to the pre-determined data collection sheet. Positive urinary tract infection showed that age of 9 patients was less than or equal to 13 months and 8 patients were more than 13 months. However, there was no significant association of UTI with age [8].

The prevalence rate of UTI among Caucasian females whose highest temperature was equal to or greater than 39°C was calculated to be 12.5%. In Jordan, a study was conducted by [9], which showed that the frequency of UTI was 3-15% of children. Studies show an association of UTI with fever in 91% cases [3-4]. The Committee concluded that a comprehensive approach to fever without focus is needed to prevent children from developing long-term complications [10].
